QGIS — Points to Path Mini Guide

How to draw lines from a CSV file

1. Required CSV structure

The CSV needs four columns:

```
line_id, point_order, latitude, longitude
```

line_id groups points into the same line. point_order defines the sequence (1 = start, 2 = end). Use longitude as X and latitude as Y.

Example:

```
line_id,point_order,latitude,longitude
1,1,51.76657175,14.32360639
1,2,51.76657175,14.32360639
2,1,51.76713535,14.32360190
2,2,51.76761099,14.32380696
```

2. How to open the Processing Toolbox

The Toolbox is not visible by default. To open it:

- Menu: Processing > Toolbox

- Keyboard shortcut: Ctrl + Alt + T

If the Processing menu does not appear at all, the plugin is disabled. Enable it here:

Plugins > Manage and Install Plugins > search 'Processing' > check the box > restart QGIS

Once the Toolbox panel is open, type 'Points to Path' in the search box at the top. The tool is located under:

```
Vector creation > Points to Path
```

3. Load the CSV as a point layer

Layer > Add Layer > Add Delimited Text Layer

- File format: CSV

- X field: longitude

- Y field: latitude

- Geometry CRS: EPSG:4326 — WGS 84

Click Add. The points will appear on the map.

4. Run Points to Path

Open the tool from the Processing Toolbox and set the following:

- Input layer: your point layer

- Order field: point_order

- Group field: line_id

- Output: choose a file or leave as temporary layer

Click Run. A new line layer will be added with one line per line_id.
